Fluoride levels in the water supply were significantly higher in the acceptor services or processes in the laboratory studies compared to the non-acceptor services and the non-acceptor facilities. This is a significant finding, particularly in the context of the acceptor services and processes, which are known to be associated with higher fluoride levels in the water supply. This finding is consistent with the findings of the other studies, which have shown that fluoride levels in the water supply are significantly higher in the acceptor services and processes compared to the non-acceptor services and processes.
